

## Long-distance optical transceivers for security applications are heat-resistant

### Overview

The transceiver contains a laser diode that converts data into light signals and vice versa, enabling high-speed data transmission at far distances. To assure transmission of data, temperatures should be kept typically below 70°C. 6 Tbps (supporting next-generation AI workloads), efficient thermal management is critical. Optical transceivers (SFP/SFP+/QSFP/QSFP28 and similar) are the backbone of modern fiber networks. While they're designed to operate within specified temperature ranges, running a module above its rated operating temperature causes measurable performance degradation and can lead to permanent. By reducing footprints, co-designing optics and electronics for greater efficiency, and adhering to industry standards, operators can reduce the impact of heat-related issues. The best way to manage heat is to produce less of it in the first place. This blog delves into the concept of Thermoelectric Coolers, their working principles, and their specific application in optical transceivers.
