

Overload Test of the Headboard

Overview

Testing is to be carried out by applying a uniform load over the surface of the headboard across the full width and up to a height of either 1600 mm, or 3/4 of the height of the headboard if it is above 2130 mm high. Selecting the right type of board is just as important as complete confidence in its performance under load. That's why we invited independent certification company DNV to witness and supervise the stress tests of our 2/3-bundle configuration headboard at our in-house tensile testing facility. They can form an integral part of a load restraint system if the product is blocked directly against them. Plant and Safety are national experts for a wide range of specialist testing services including Mechanical Tensile and Compression Testing. By inspecting the thermal gradients of all three phases side-by-side, technicians can quickly spot performance anomalies on individual legs due to unbalance or overloading. Electrical unbalance can be caused by several different sources: a power delivery problem, low voltage on one leg, or an. all new trailers.
