

Pre-reserved length on each side of the fiber optic cable connector

Overview

Each of these exercises involves terminating a tight buffer fiber or simplex fiber optic cable with a common type of connector.

Key Takeaways

The typical pre-reserved or preparation length for fiber optic connectors ranges from 10 mm to 30 mm of exposed fiber beyond the jacket, depending on connector type and termination method.

General Guidelines
When preparing a fiber optic cable for connectorization, a pre-reserved length of fiber must be stripped and cleaned to allow proper insertion into the connector ferrule or splice assembly. This length ensures:

- Adequate fiber for polishing or cleaving
- Proper alignment in the ferrule
- Slack for handling and routing without exceeding bend radius limits
- Room for re-termination if needed

Typical Preparation Lengths

- LC connectors: Usually require 10-15 mm of exposed fiber beyond the jacket for insertion into the 1.25 mm ferrule and epoxy or mechanical splice assembly .

- SC connectors: Typically need 15–20 mm of exposed fiber for the 2.5 mm ferrule and proper termination .

- ST connectors: Similar to SC, around 15–20 mm of fiber is prepared for insertion into the bayonet-style ferrule .

- Splice-on connectors (SOC): May require 20–30 mm of fiber to allow for fusion splicing or mechanical splice before connector assembly .

Considerations for Field Termination

- Singlemode fibers: Require more precise cleaving and polishing; preparation lengths are critical to maintain low insertion loss and high return loss .

- Multimode fibers: Slightly more forgiving; field terminations often use mechanical connectors with similar prep lengths .

- Slack and routing: Additional fiber length (slack) should be reserved inside enclosures or patch panels to allow for future re-termination or relocation, typically 0.5–1 meter per side in structured cabling installations .

Best Practices

- Follow manufacturer instructions: Each connector type and vendor may specify exact prep lengths.

- Use proper tools: Fiber strippers, cleavers, and cleaning supplies are essential to avoid micro-bends or contamination .

- Maintain bend radius: Avoid sharp bends in the pre-reserved fiber to prevent signal loss.

- Label and document: Keep track of fiber lengths and connector types for maintenance and troubleshooting. By adhering to these guidelines, fiber optic terminations achieve low insertion loss, minimal reflectance, and reliable mechanical performance, ensuring optimal network operation .
